

Low Fidelity Prototyping

Scenario 1:

The app will have users importing all their account information to import their libraries. If a user has an extensive library spread across 3 marketplaces alone with more minor marketplaces with 1 game, this application will unify it for them. They will first input their accounts for a platform, then the application will fetch their library, and showcase it.

Scenario 2:

The app will update/download games for users across different platforms. Let's say it was a good week for a user and many games in their library need updates. Rather than updating games in each launcher for their market, the user can manage it all from the app. The user would go to the downloads tab and check for updates and wait for them to download.

Scenario 3:

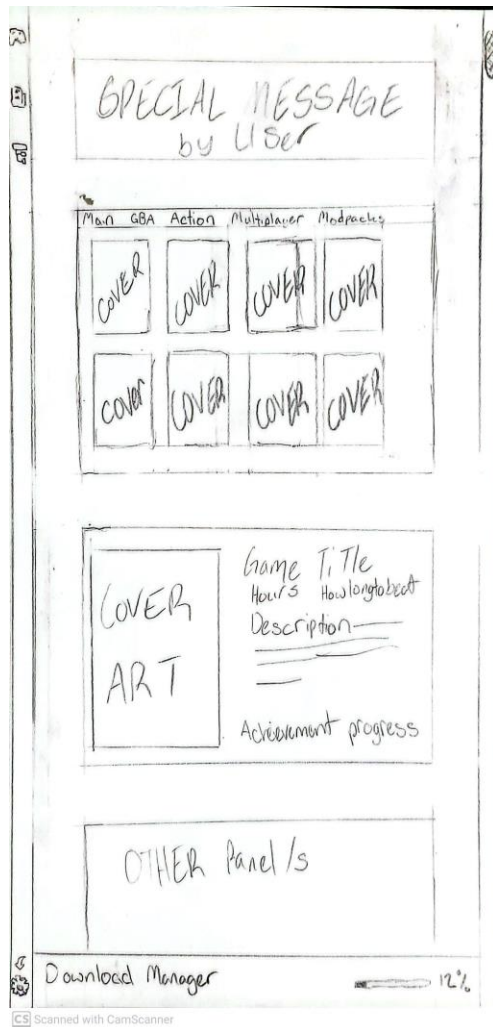

Let's say a user already has a game launcher, every time they launch or close games they must close and open the window along with moving it around, so it doesn't get in the way of other apps. Rather than performing like a usual window, it opens when you move your mouse all the way to the side of the screen, providing an easier way to access. It also closes once you remove your mouse from the application, not having to think about how it interferes with other windows on your screen.

Prototype Use Data:

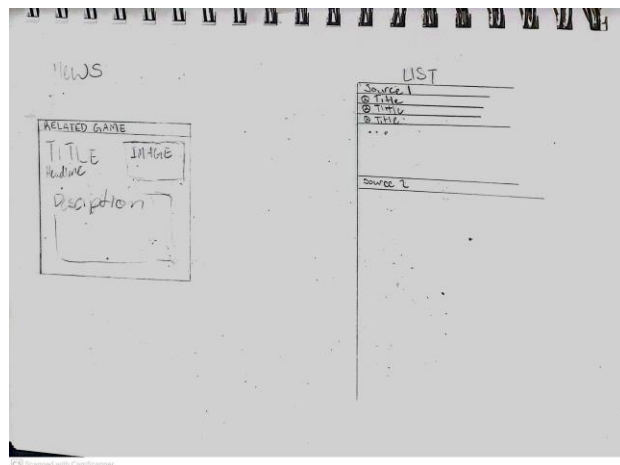

The tasks the prototype will support are importing a user's library and displaying it, displaying game information, and using the download manager. The user will sign into an account and use the application to install a small game. The data we will collect is how it could be made easier to use along with the user's thoughts on the user interface.

This is the current lo-fi prototype for the application.

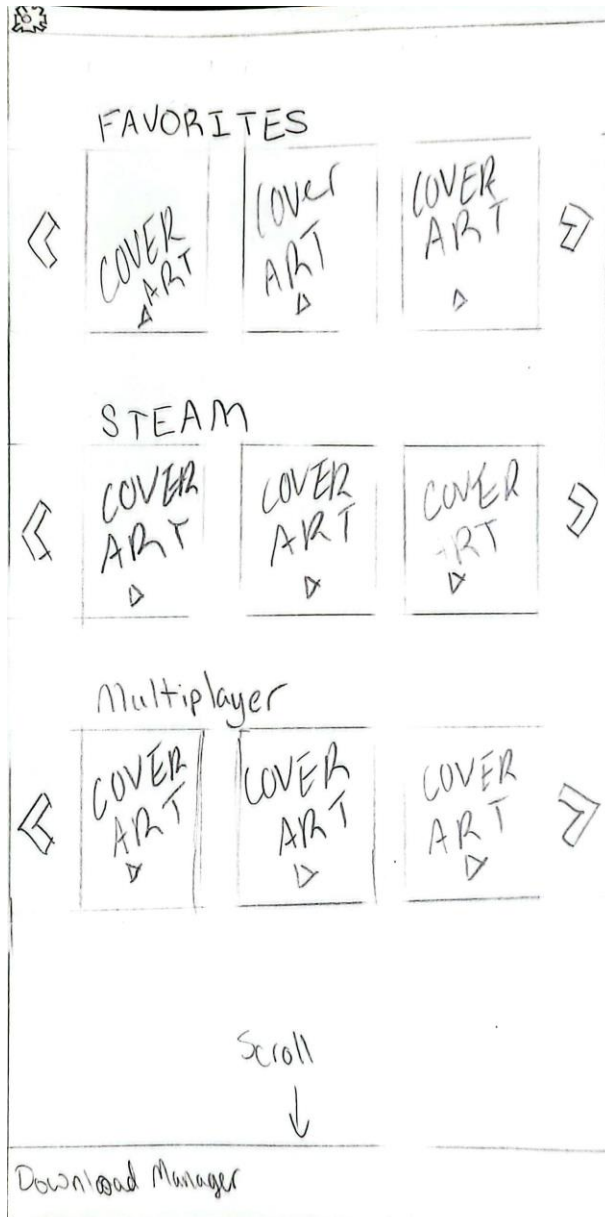

The image is the main screen with 3 tabs on the top left: the main screen,

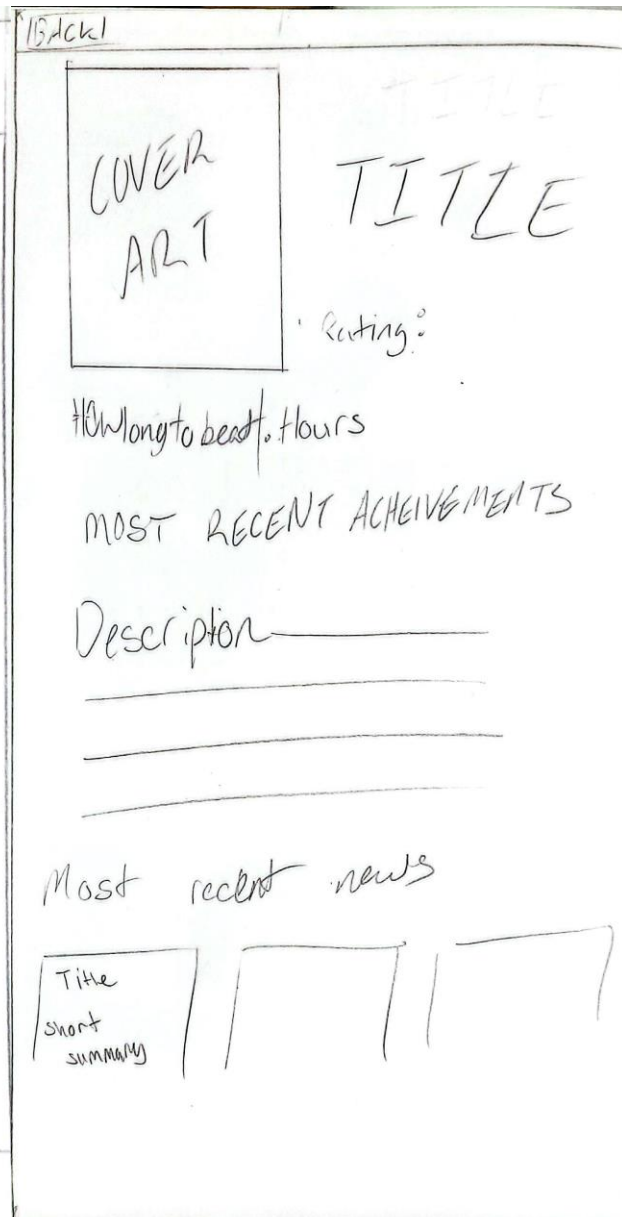

the news, and the list view (both news and list elements given in the bottom image).

This is version 2, the main screen (left) is similar to streaming app browsing and once you click on a game, you are taken to a different submenu (right).
